
CUDA OPTIMIZATION, PART 2

NVIDIA Corporation

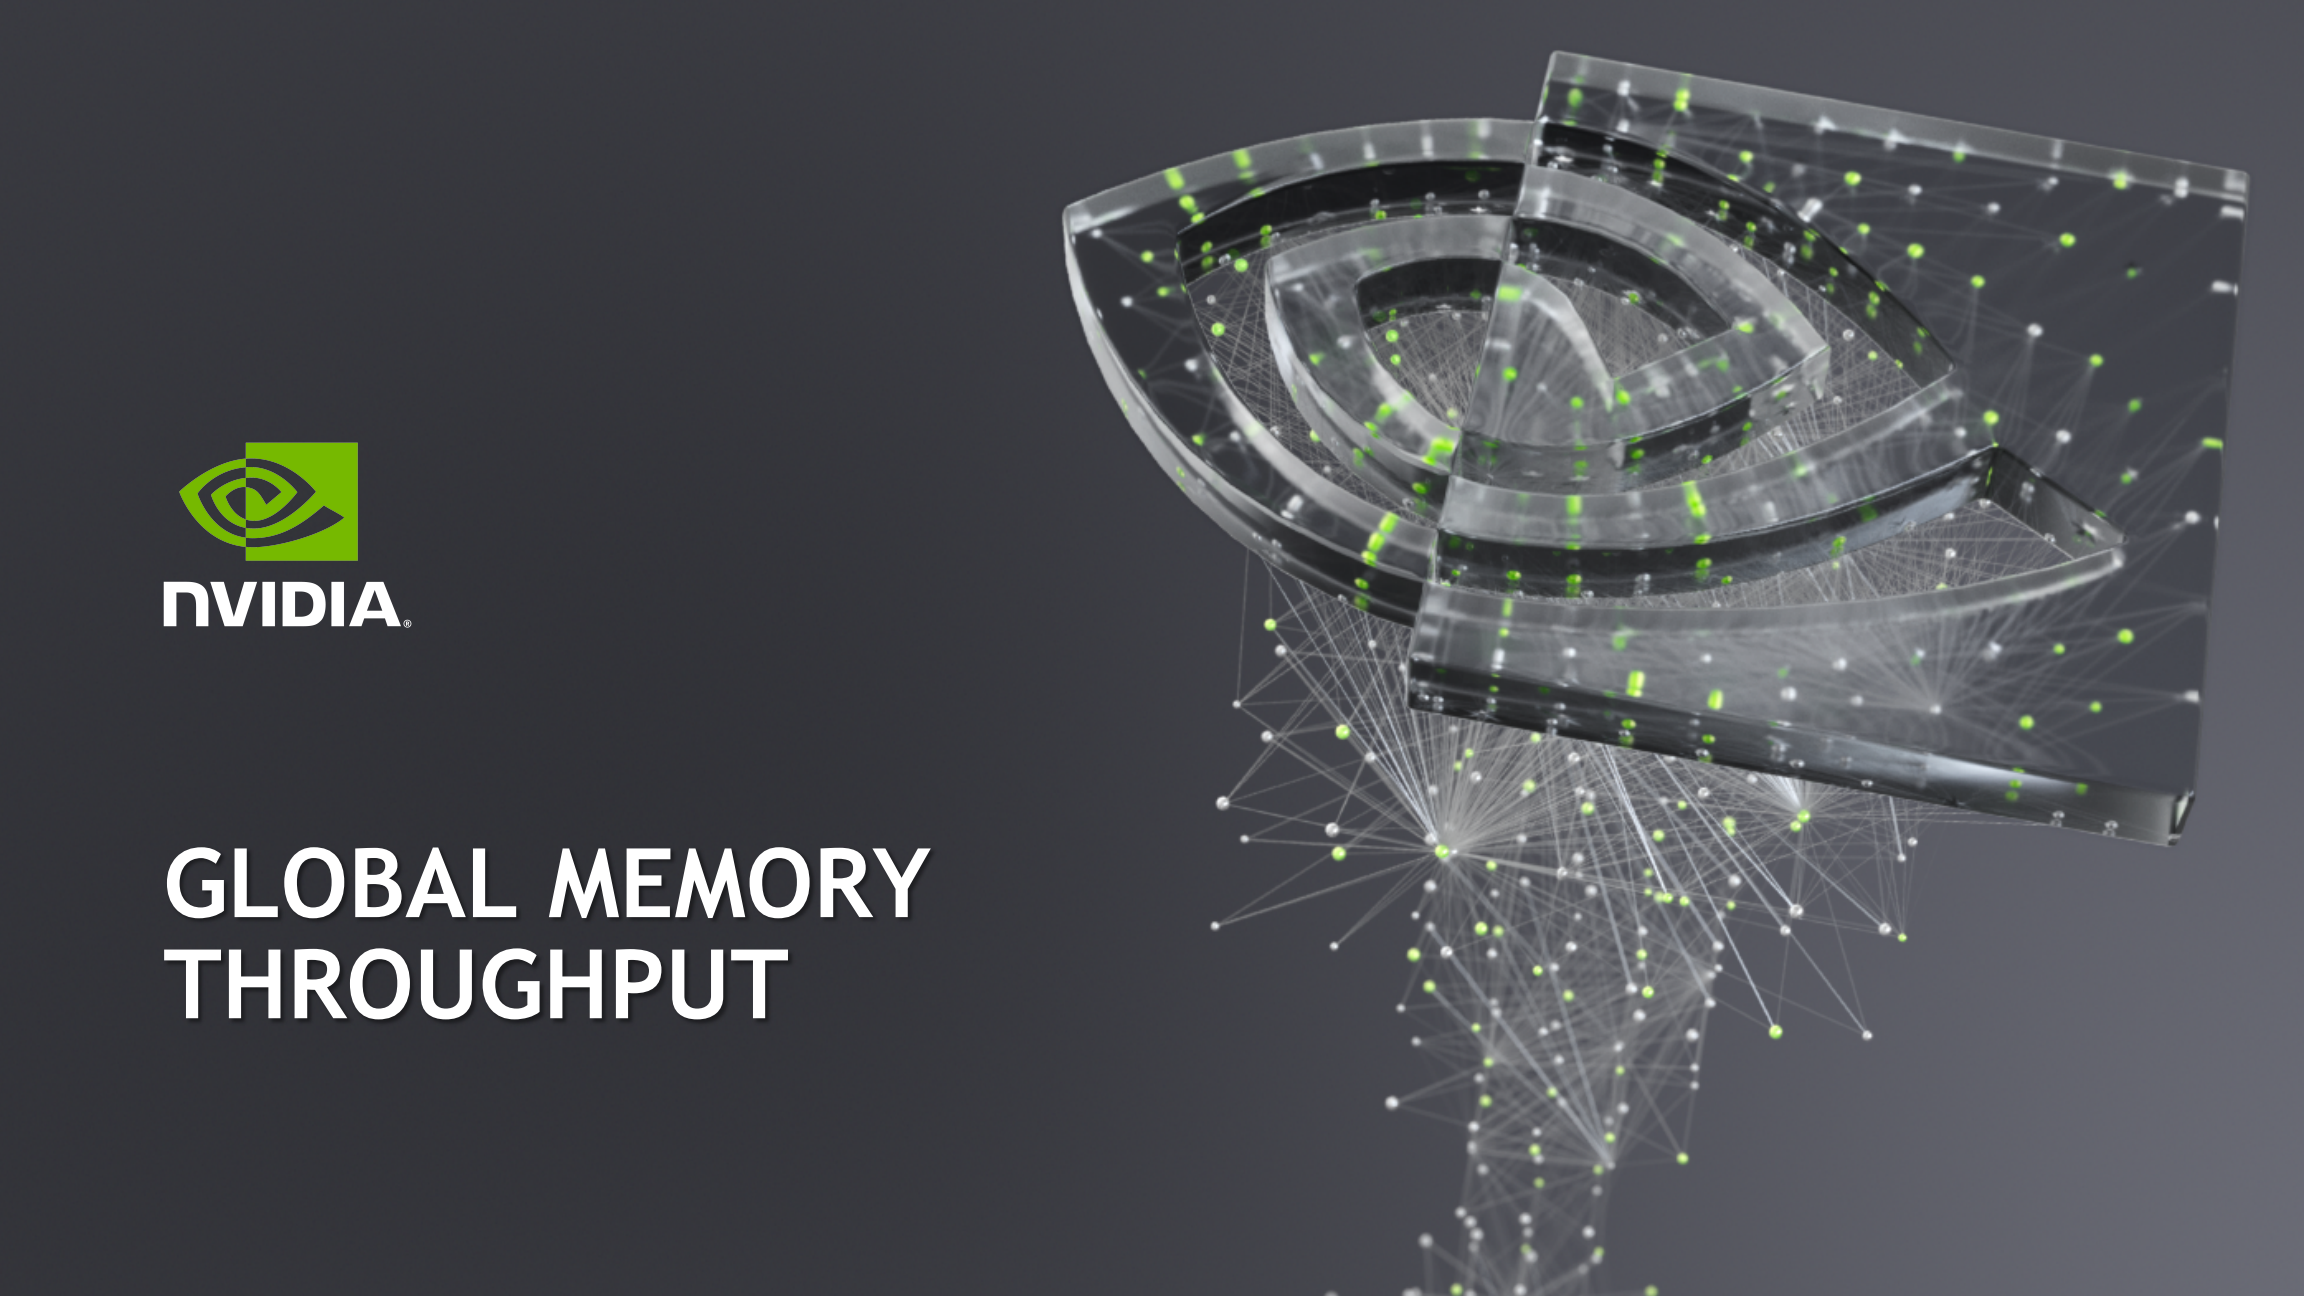
OUTLINE

- Architecture:

  Kepler/Maxwell/Pascal/Volta

- Kernel optimizations
  - Launch configuration
- Part 2 (this session):
  - Global memory throughput
  - Shared memory access

Most concepts in this presentation apply to *any* language or API on NVIDIA GPUs



GLOBAL MEMORY THROUGHPUT

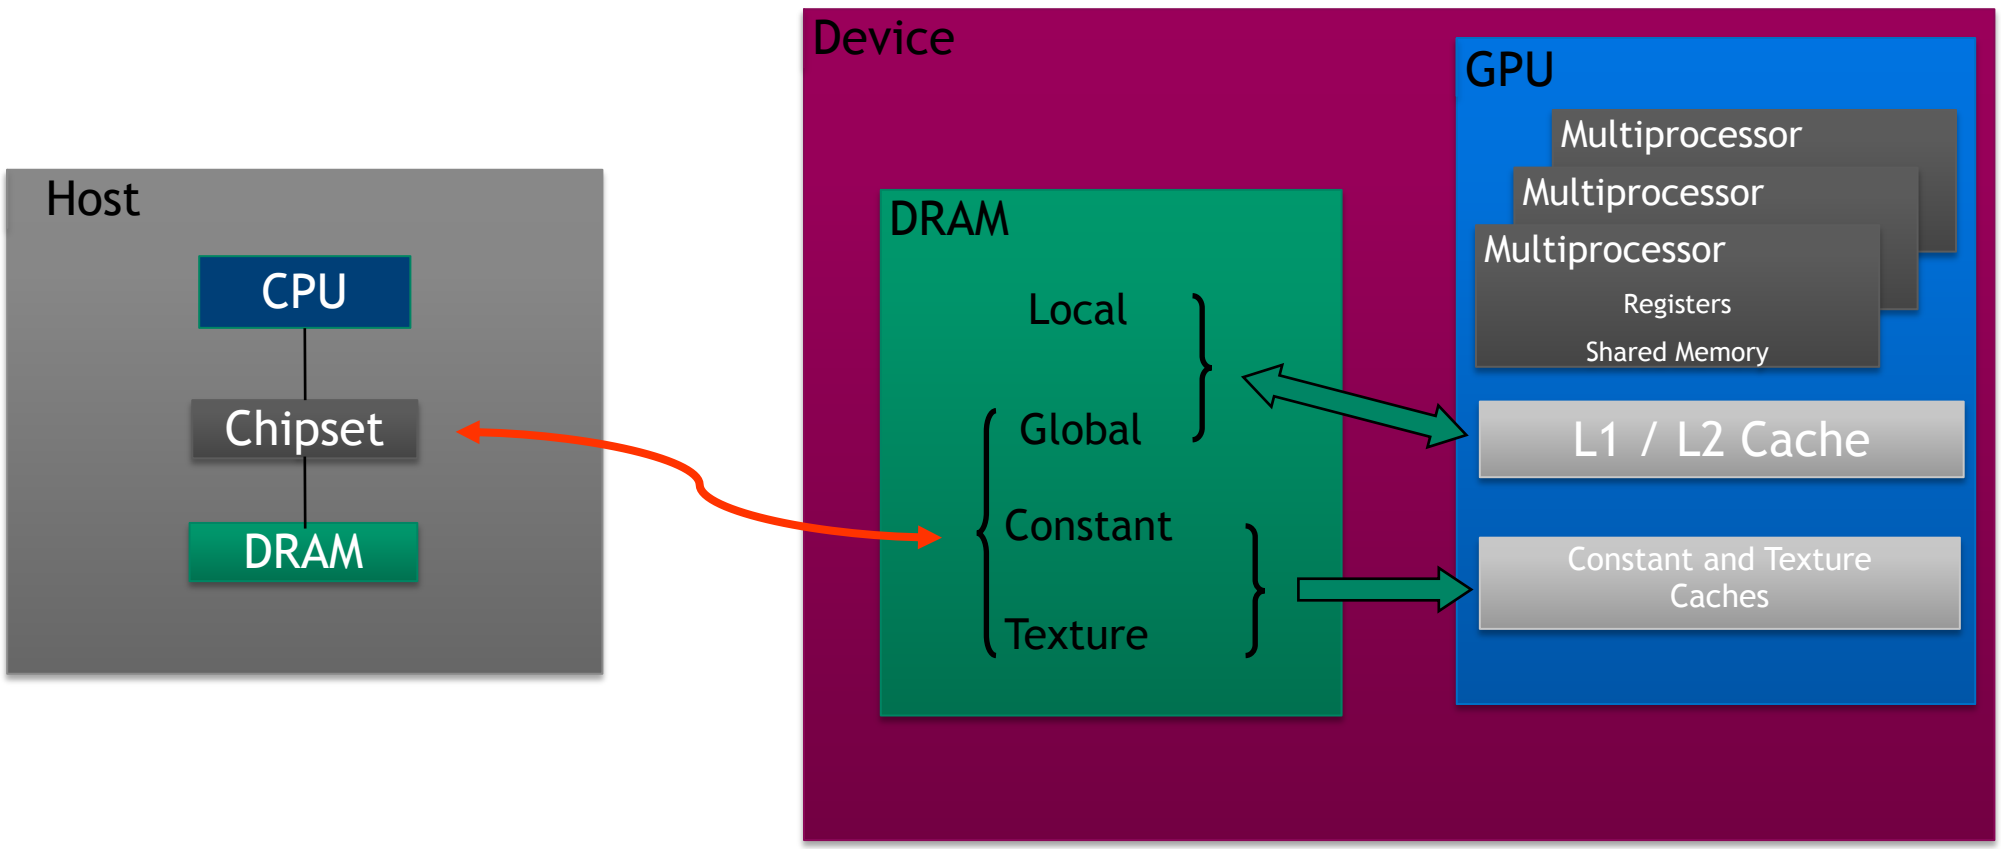
MEMORY HIERARCHY REVIEW

- Local storage
  - Each thread has own local storage
  - Typically registers (managed by the compiler)
- Shared memory / L1
  - Program configurable: typically up to 48KB shared (or 64KB, or 96KB…)
  - Shared memory is accessible by threads in the same threadblock
  - Very low latency
  - Very high throughput: >1 TB/s aggregate

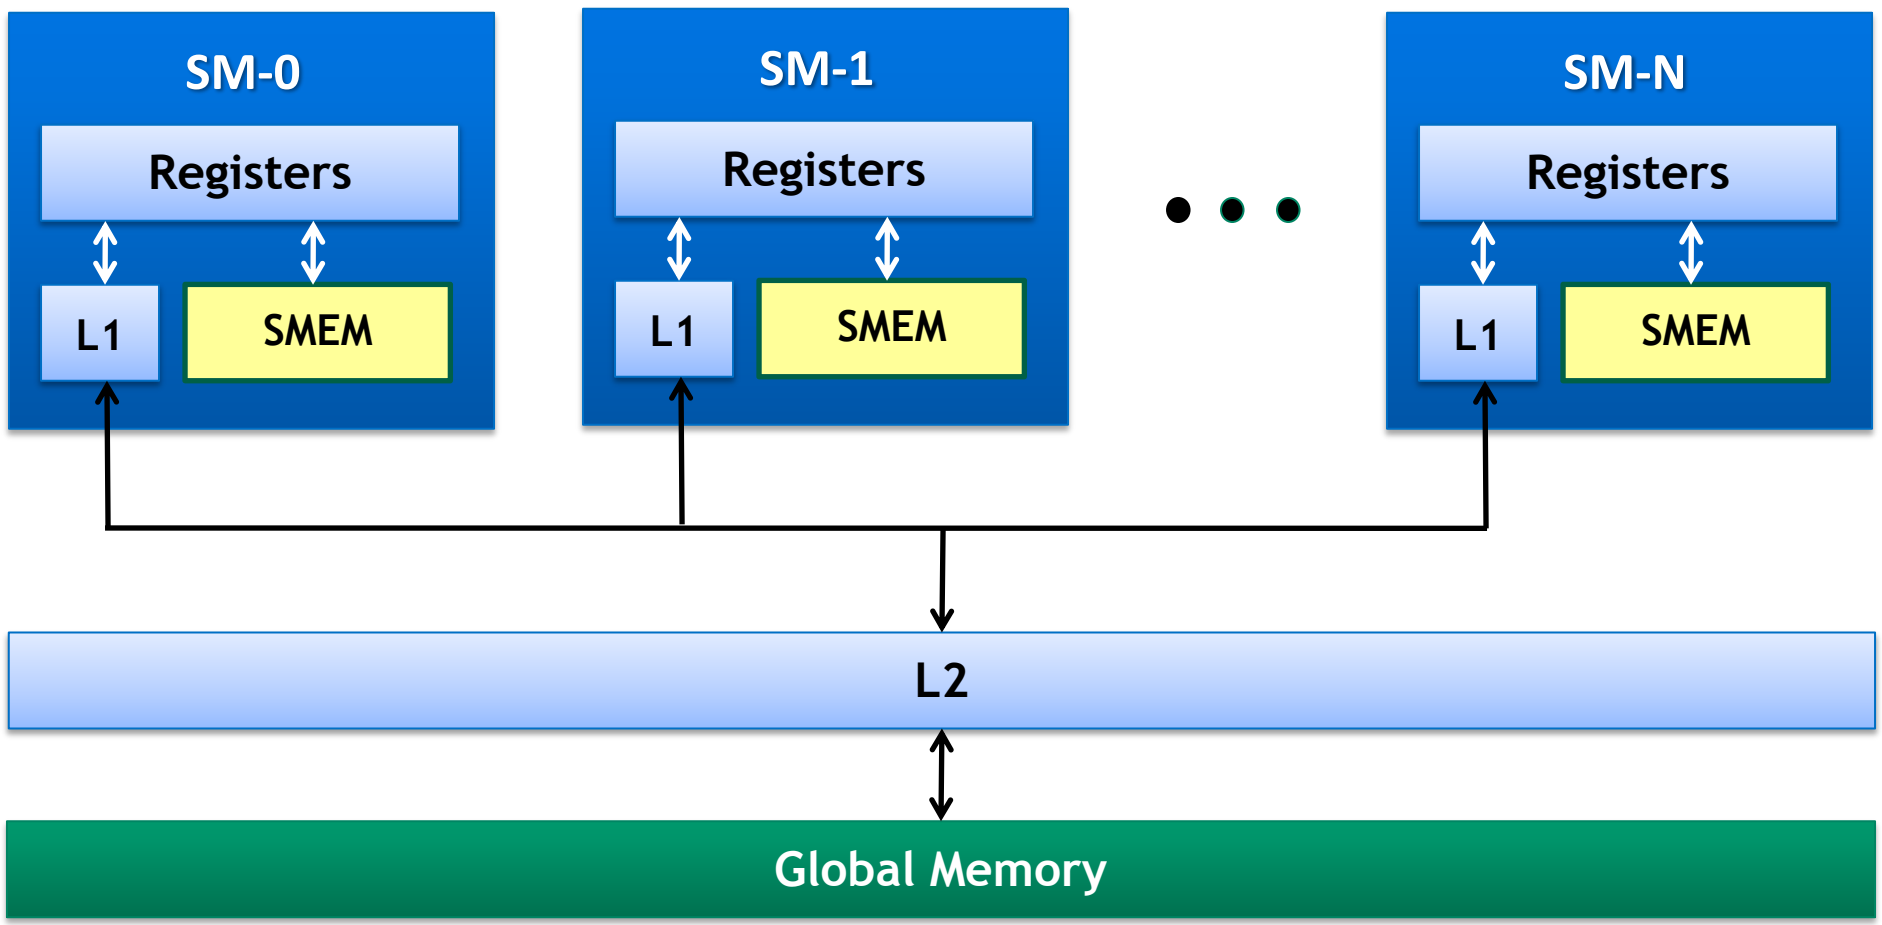
MEMORY HIERARCHY REVIEW

- L2
  - All accesses to global memory go through L2, including copies to/from CPU host
- Global memory
  - Accessible by all threads as well as host (CPU)
  - High latency (hundreds of cycles)
  - Throughput: up to ~900 GB/s (Volta V100)

MEMORY ARCHITECTURE



MEMORY HIERARCHY REVIEW



GMEM OPERATIONS

- Loads:
  - Caching
    - Default mode
    - Attempts to hit in L1, then L2, then GMEM
    - Load granularity is 128-byte line
- Stores:
  - Invalidate L1, write-back for L2

GMEM OPERATIONS

- Loads:
  - Non-caching
    - Compile with -Xptxas -dlcm=cg option to nvcc
    - Attempts to hit in L2, then GMEM

      Do not hit in L1, invalidate the line if it's in L1 already
    - Load granularity is 32-bytes

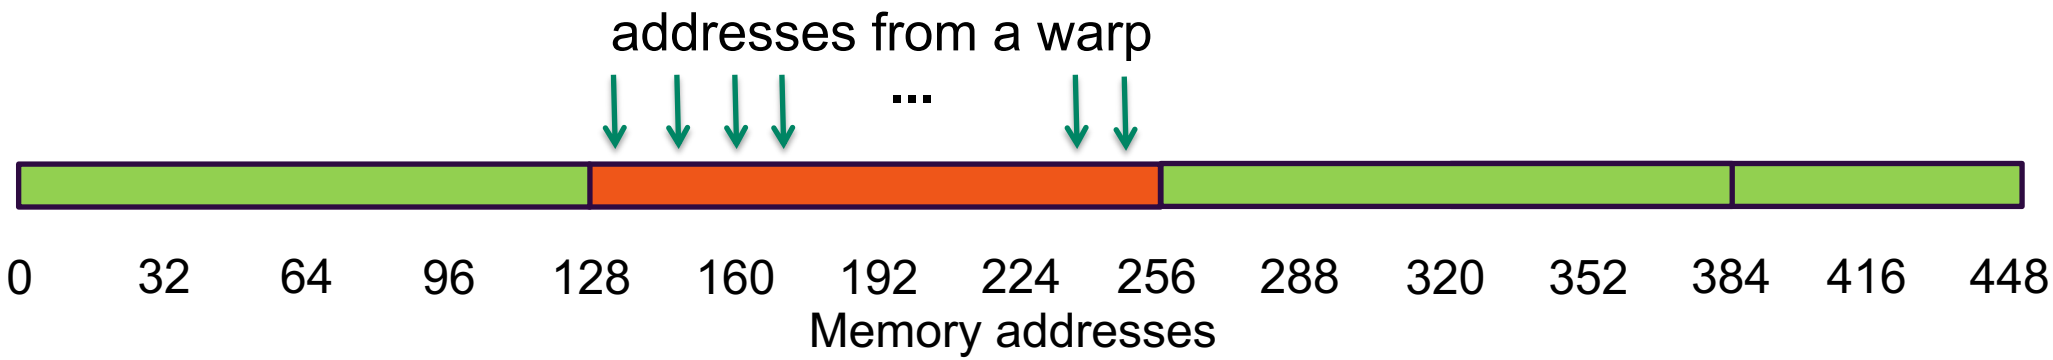
We won't spend much time with non-caching loads in this training session

LOAD OPERATION

- Memory operations are issued per warp (32 threads)
  - Just like all other instructions
- Operation:
  - Threads in a warp provide memory addresses
  - Determine which lines/segments are needed
  - Request the needed lines/segments

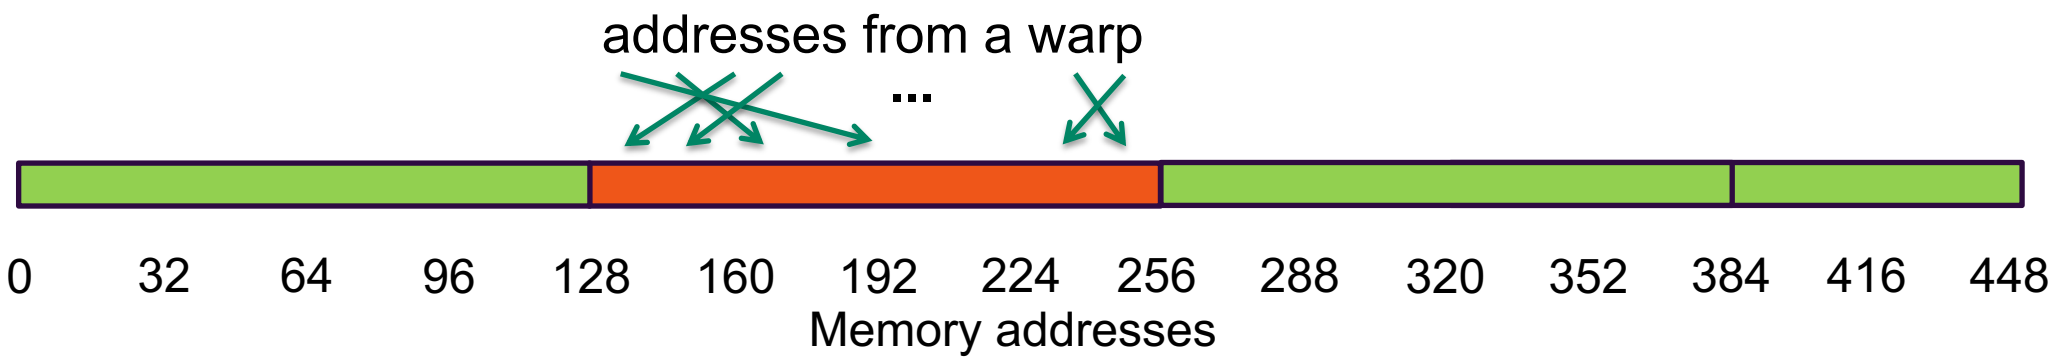
CACHING LOAD

- Warp requests 32 aligned, consecutive 4-byte words
- Addresses fall within 1 cache-line
  - Warp needs 128 bytes
  - 128 bytes move across the bus on a miss
  - Bus utilization: 100%
  - int c = a[idx];



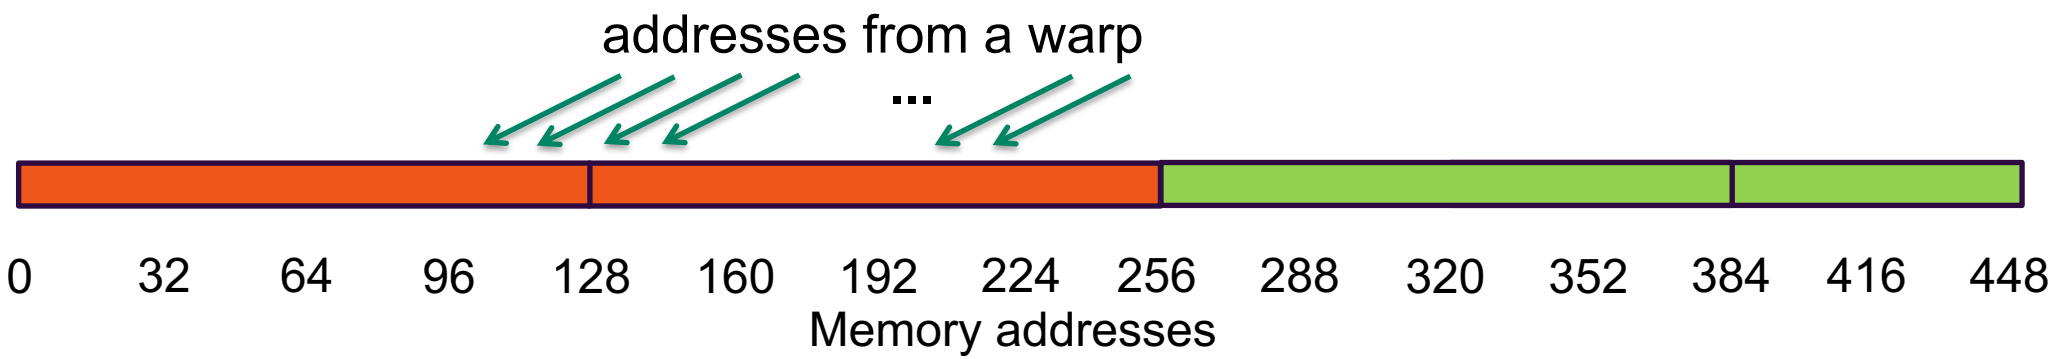
CACHING LOAD

- Warp requests 32 aligned, permuted 4-byte words
- Addresses fall within 1 cache-line
  - Warp needs 128 bytes
  - 128 bytes move across the bus on a miss
  - Bus utilization: 100%
  - int c = a[rand()%warpSize];



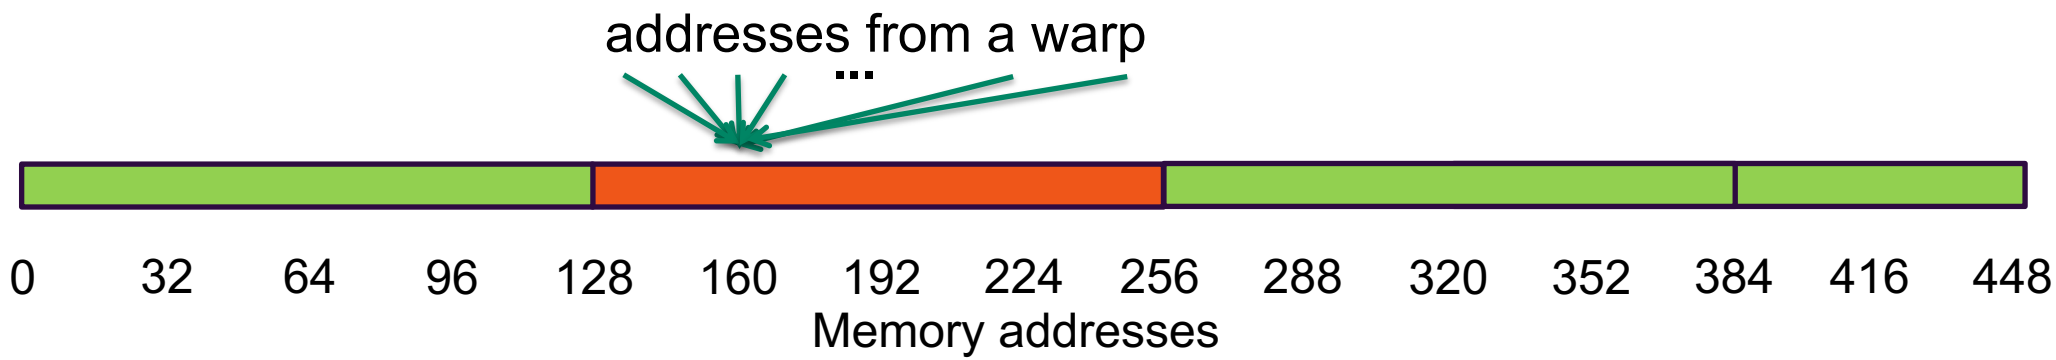
CACHING LOAD

- Warp requests 32 misaligned, consecutive 4-byte words
- Addresses fall within 2 cache-lines
  - Warp needs 128 bytes
  - 256 bytes move across the bus on misses
  - Bus utilization: 50%
  - int c = a[idx-2];



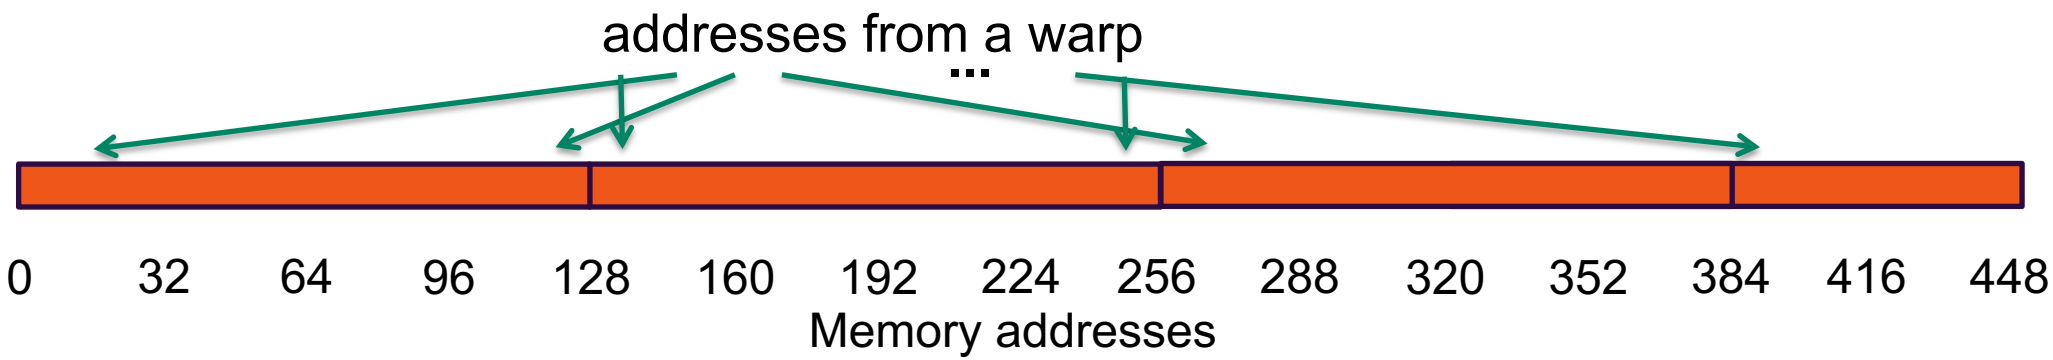
CACHING LOAD

- All threads in a warp request the same 4-byte word
- Addresses fall within a single cache-line
  - Warp needs 4 bytes
  - 128 bytes move across the bus on a miss
  - Bus utilization: 3.125%
  - int c = a[40];



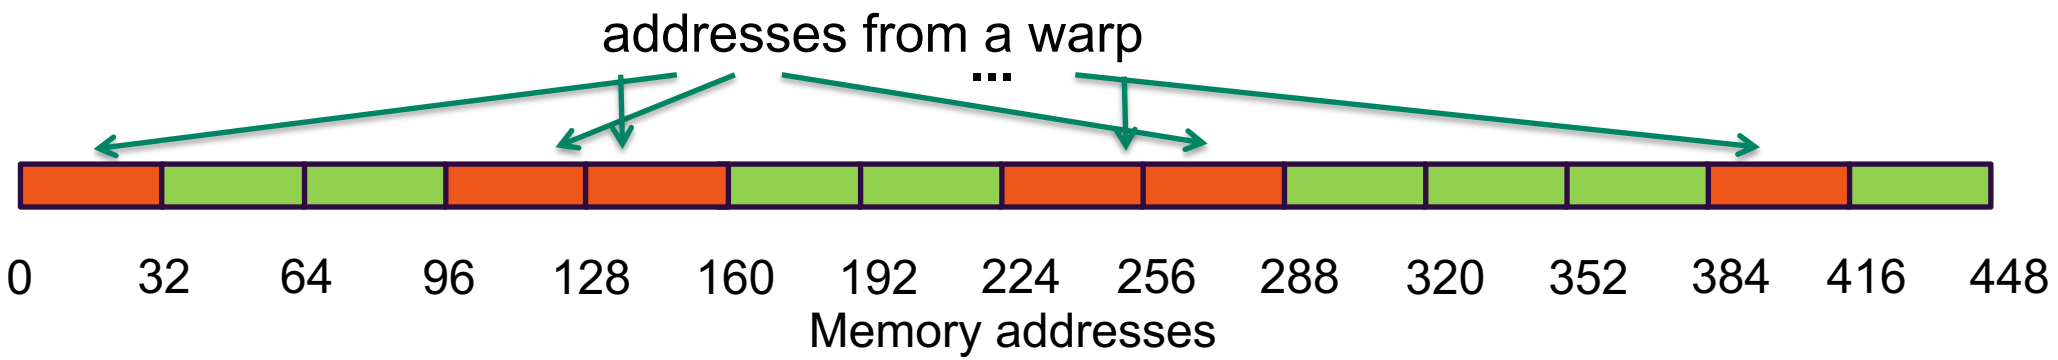
CACHING LOAD

- Warp requests 32 scattered 4-byte words
- Addresses fall within N cache-lines
  - Warp needs 128 bytes
  - N*128 bytes move across the bus on a miss
  - Bus utilization: 128 / (N*128) (3.125% worst case N=32)
  - int c = a[rand()];



NON-CACHING LOAD

- Warp requests 32 scattered 4-byte words
- Addresses fall within N segments
  - Warp needs 128 bytes
  - N*32 bytes move across the bus on a miss
  - Bus utilization: 128 / (N*32) (12.5% worst case N = 32)
  - int c = a[rand()]; -Xptxas -dlcm=cg



GMEM OPTIMIZATION GUIDELINES

- Strive for perfect coalescing
  - (Align starting address - may require padding)
  - A warp should access within a contiguous region
- Have enough concurrent accesses to saturate the bus
  - Process several elements per thread
    - Multiple loads get pipelined
    - Indexing calculations can often be reused
  - Launch enough threads to maximize throughput
    - Latency is hidden by switching threads (warps)
- Use all the caches!

SHARED MEMORY

SHARED MEMORY

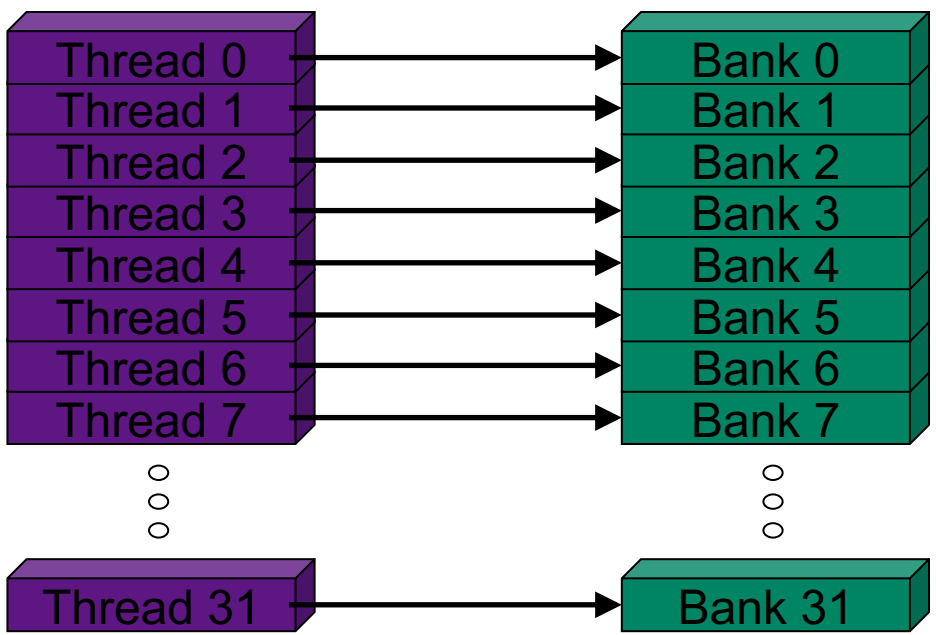
- Uses:
  - Inter-thread communication within a block
  - Cache data to reduce redundant global memory accesses
  - Use it to improve global memory access patterns
- Organization:
  - 32 banks, 4-byte wide banks
  - Successive 4-byte words belong to different banks

SHARED MEMORY

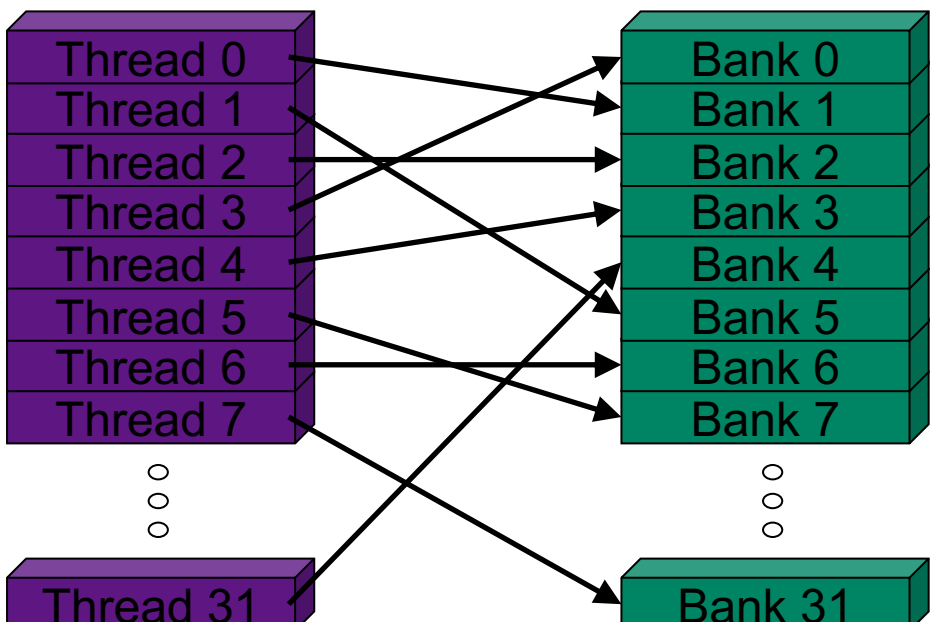
- Performance:
  - Typically: 4 bytes per bank per 1 or 2 clocks per multiprocessor
  - shared accesses are issued per 32 threads (warp)
  - serialization: if *N* threads of 32 access different 4-byte words in the same bank, *N* accesses are executed serially
  - multicast: *N* threads access the same word in one fetch
    - Could be different bytes within the same word

BANK ADDRESSING EXAMPLES

No Bank Conflicts

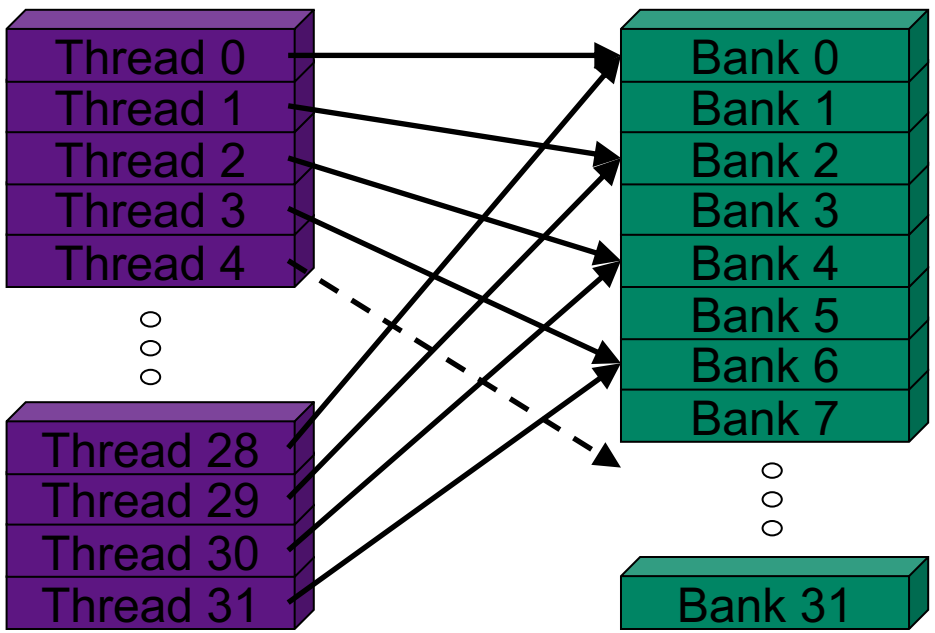


No Bank Conflicts

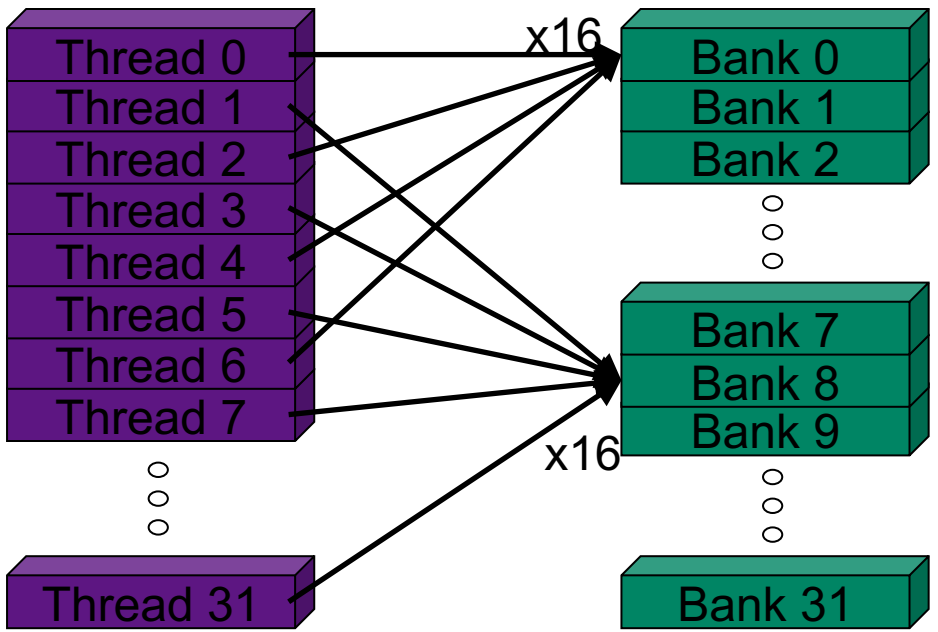


BANK ADDRESSING EXAMPLES

2-way Bank Conflicts



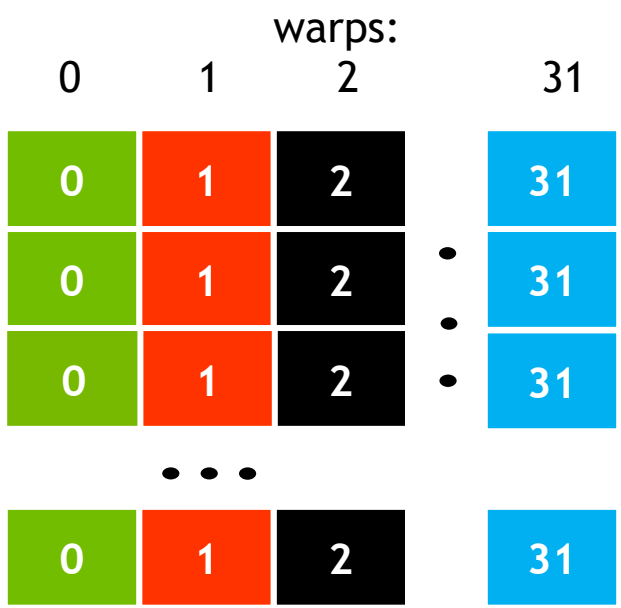
16-way Bank Conflicts



SHARED MEMORY: AVOIDING BANK CONFLICTS

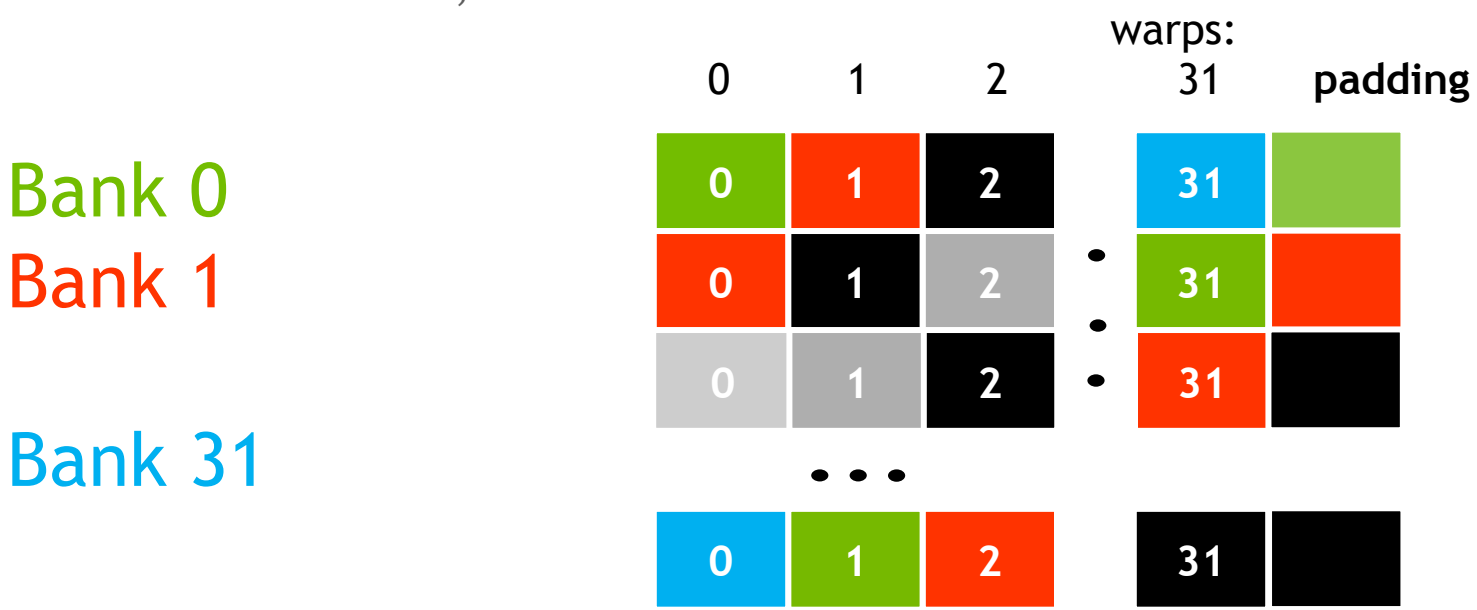
- 32x32 SMEM array
- Warp accesses a column:
  - 32-way bank conflicts (threads in a warp access the same bank)

Bank 0
Bank 1
...
Bank 31



SHARED MEMORY: AVOIDING BANK CONFLICTS

- Add a column for padding:
  - 32x33 SMEM array
- Warp accesses a column:
  - 32 different banks, no bank conflicts



SUMMARY

- Kernel Launch Configuration:
  - Launch enough threads per SM to hide latency
  - Launch enough threadblocks to load the GPU
- Global memory:
  - Maximize throughput (GPU has lots of bandwidth, use it effectively)
- Use shared memory when applicable (over 1 TB/s bandwidth)
- Use analysis/profiling when optimizing:
  - “Analysis-driven Optimization” (future session)

FUTURE SESSIONS

- Atomics, Reductions, Warp Shuffle
- Using Managed Memory
- Concurrency (streams, copy/compute overlap, multi-GPU)
- Analysis Driven Optimization
- Cooperative Groups

HOMEWORK

- Log into Summit (ssh username@home.ccs.ornl.gov -> ssh summit)
- Clone GitHub repository:
  - Git clone git@github.com:olcf/cuda-training-series.git
- Follow the instructions in the readme.md file:
  - https://github.com/olcf/cuda-training-series/blob/master/exercises/hw4/readme.md
- Prerequisites: basic linux skills, e.g. ls, cd, etc., knowledge of a text editor like vi/emacs, and some knowledge of C/C++ programming
